Synthetic Methodologies for Developing Lanthanide-Based Single-Molecule Magnets

Molecules that exhibit the super-paramagnet-like property of slow magnetization relaxation and thus behave as magnets below their magnetic blocking temperature. Single-Molecule Magnets (SMMs) are promising candidates for molecular electronics such as high-density memory storage and quantum computers. Yet, the design of high-performance SMMs has been an ongoing challenge for the last three decades. Low-coordinate lanthanide complexes with strong magnetic anisotropy could afford high-performance SMMs but are challenging to synthesize. Now, through ligand design, a near-linear pseudo-two-coordinate Yb(III), Eu(II) complexes that exhibits slow magnetic relaxation are reported.^{1,2} The complex has a large ground-state splitting arising from the crystal field imposed by the ligands. These results represent an important step towards SMMs with record blocking temperatures.
